

SFWR ENG 3A04: Software Design II

Dr. Ridha Khedri

Department of Computing and Software, McMaster University
Canada L8S 4L7, Hamilton, Ontario

Term 2

Acknowledgments: Material based on *Software Architecture Design* by Tao et. al. (Chapter 6)

Hierarchy Architecture Overview

- In this architectural style, the system is viewed as a hierarchical structure
- The software system is decomposed into **functional modules** (sub-systems)
- The modules at different levels are **connected** by **explicit method invocations**
- A lower level module provides services to its adjacent upper level modules
- In procedure orientation, the lower level function and procedures may be organized in a header file or library

Hierarchy Architecture Overview

- In the object orientation, the lower level services may be organized in a package of classes
- Many system software (e.g., Unix) are built by hierarchical architecture
- The services at lower levels provide more specific fundamental utility service
- The middle layer provides all business logic or core processing services
- The upper layer provides user with interface
- Each layer is supported by its lower layer and provides service interface to its upper layer

Hierarchy Architecture Overview

- The HA is characterized by explicit method invocation (call-and-return) connection styles
- It is used in the organization of class library
- It can be applied to procedure-oriented design, object-oriented design, component-oriented design, domain-specific design, and many others
- It is hard to see any software that only uses one type architectural style
- The hierarchical structure is one of the **most popular styles** that often combine with other styles

Hierarchy Architecture

Main/Subroutine Software Architecture

- The **main/subroutine design architecture** has dominated the software design methodologies for very long time
- Its purpose is to have **maximum reuse of subroutines** and make individual **subroutine be developed independently**
- In the classical procedure orientation, often all the data are shared by related subroutines at lowest level
- In the object orientation, the data is encapsulated in each individual object
- Often M/S style is referred to as the traditional style

Hierarchy Architecture

Main/Subroutine Software Architecture

- A system is decomposed into subroutines hierarchically according to the desired functionality of the system
 - Behaviour hiding (secrets = input formats, screen formats, messages)
 - Software decision hiding (secrets= algorithms and data structures)
 - Machine hiding (secrets= hardware machine, virtual machine, interfaces, etc.)
- The refinements are conducted vertically until the decomposed subroutine is simple enough

Hierarchy Architecture

Main/Subroutine Software Architecture

- The main program is the program driver that has a mater control over the sequencing of its subroutines
- How to map a requirement specification to the Main/Subroutine design structure?
 - Start from a data flow view (Data Flow Diagram) of the requirements
 - We need to find transform or transaction flows:
 - Transform Flow (flow feeds in an external format, it is transformed into an internal format, and then carried out)
 - Transaction Flow (evaluates its incoming data value, and decides on the path to follow)

Hierarchy Architecture

Main/Subroutine Software Architecture

- How to map a requirement specification to the Main/Subroutine design structure? (Continued)
 - A transform flow is mapped to an M/S architecture with a **controlling module** for incoming, transform and outgoing information processing
 - A transaction center is located at the fork origin of action paths
 - Classify each action path to transform or transaction flows
 - The transaction centre becomes a **dispatcher control module**
 - Factoring analysis continues until each module in the software architecture has its sole responsibility

Hierarchy Architecture

Main/Subroutine Software Architecture

- **Benefits**

- Easy to decompose the system based on the definition of the tasks in a top down refinements manner
- This architecture can still be used in a sub-system of OO Design

- **Limitation**

- Globally shared data in classical main/subroutines are vulnerable
- Tight coupling may cause ripple impacts compared to OO Design

Hierarchy Architecture

Master/Slaves Software Architecture

Master/Slaves Software Architecture

- The Master/Slaves architecture is a variant of the main/subroutine architecture style
- It supports **fault tolerance** and **system reliability**
- The slaves provide replicated services to the master
- The master selects a particular result among slaves by certain selection strategy
- The slaves may perform the same functional task by different algorithms and methods

Hierarchy Architecture

Master/Slaves Software Architecture

- This architecture is suitable for parallel computing and accuracy of computation
 - All slaves can be executed in parallel
 - A task is delegated to several different implementations, inaccurate results can be detected
- Applicable Design Domains
 - Software system where the liability is critical
 - Software system where performance is critical (to a certain limit –communication overhead–)

Hierarchy Architecture

Layered Architecture

Layered Architecture

- System is decomposed into a number of higher and lower layers
- Each layer consists of a group of related
 - classes in a format of package or deployed component (OOD)
 - a group of subroutines in the format of method library or header file
- Each layer should have its own sole responsibility for the entire system

Software
Architecture

Master/Slaves
Software
Architecture

Layered
Architecture

Virtual Machine

Hierarchy Architecture

Layered Architecture

- A request to layer $i + 1$ invokes the services provided by the layer i via the later interface
- The response may go back to the layer $i + 1$ if the task is completed by this layer i
- Otherwise, layer i continually invokes the layer $i - 1$ below for services
- The interface of each layer encapsulates all detail service implementations in the current layer or below

Architecture

**Layered
Architecture**

Virtual Machine

Hierarchy Architecture

Layered Architecture

- The request from higher layer to the layer below is made via the method invocation and the response goes back up via the method return
- Each layer has two interfaces
 - up interface provides services to its upper layer
 - low interface requires services from its lower layer
- In a **pure layered hierarchy**, each layer only provides services to the adjacent upper layer directly and only requests services from the adjacent layer directly below

Architecture

Virtual Machine

Hierarchy Architecture

Layered Architecture

- Higher layer provides more generic or application oriented services (abstract)
- Lower layer provides more specific utility type services
- To encapsulate all the services in one layer, we can deploy each layer in a component format (such as a JAR file (Java ARchive)))
- A JAR file is a compressed file which is deployed as a component of a package

Layered
Architecture

Virtual Machine

Hierarchy Architecture

Layered Architecture

- A jar file includes all the service classes from lower level plus other related classes provided in the same layer and provided by Java API
 - The Java API is the set of classes included with the Java Development Environment
 - These classes are written using the Java language and run on the JVM
 - The Java API includes everything from collection classes to GUI classes

Hierarchy Architecture

Layered Architecture

A simple software system may consist of two layers
(Interaction & Processing)

- **Interaction Layer**

- It provides user Interfaces to clients
- It takes requests
- It validates and forwards request to processing layer for processing
- It responds to clients

- **Processing Layer**

- It gets the forwarded requests and performs business logic process
- It accesses database
- It returns the results to its upper layer
- It lets upper layer respond to clients (since the upper layer has the GUI interface responsibility)

Hierarchy Architecture

Layered Architecture

- Applicable Design Domains

- Any system that can be divided between the application specific portions and platform specific portions
- Applications that have clean divisions between **core services**, **critical services**, **user interface services**
- Applications that have a **number of classes that are closely related to each other** so that they can be grouped together to provide the services to others.

- Benefit

- Incremental software development based on increasing levels of abstraction
- Enhanced independence of layers
- Enhanced reusability
- Component-based technology is a suitable technology to implement the layered structure (plug-and-play)
- Promotion of portability: each layer can be an abstract machine deployed independently

Hierarchy Architecture

Layered Architecture

- Limitations

- Lower runtime performance (a client's request/response goes through many layer)
- Performance concerns on overhead on the data marshaling and buffering by each layer
- Many applications can not fit this architecture
- Exception and error handling is an issue in the layered architecture

- Related architecture

- Repository, client/server, virtual machine

Hierarchy Architecture

Virtual Machine

Virtual Machine

- It is built on an existing system
- It separates a programming language, hardware language, or application from a physical execution platform
- It plays the role of an **emulation software**
 - It provides an emulation of the functions of one system using a different system
 - It allows exact reproduction of external behavior of a system
